Chapter 1

Introducing ABEL

ABEL (A Better EiffelStore Library) is an object-oriented persistence library written in Eiffel and aiming at seamlessly integrating various kinds of data stores.

1.1 Setting things up

ABEL is shipped with EiffelStudio in the *unstable* directory. You can get the latest code from the SVN directory [1].

If you want to modify the sample code used in this tutorial, just check out the tutorial code from SVN [2].

1.2 Getting started

We will be using *PERSON* objects to show the usage of the API. In the source code below you will see that ABEL handles objects "as they are", meaning that to make them persistent you don't need to add any dependencies to their class source code.

class *PERSON*

3 **create**
   make

---

[1]`https://svn.eiffel.com/eiffelstudio/trunk/Src/unstable/library/persistency/abel`
[2]`https://svn.eiffel.com/eiffelstudio/trunk/Src/unstable/library/persistency/abel/sample/tutorial_api`

```eiffel
 6  feature {NONE} -- Initialization

      make (first, last: STRING)
 9        -- Create a newborn person.
        require
          first_exists: not first.is_empty
12        last_exists: not last.is_empty
        do
          first_name := first
15        last_name := last
          age:= 0
        ensure
18        first_name_set: first_name = first
          last_name_set: last_name = last
          default_age: age = 0
21      end

    feature -- Basic operations
24
      celebrate_birthday
        -- Increase age by 1.
27      do
          age:= age + 1
        ensure
30        age_incremented_by_one: age = old age + 1
        end

33  feature -- Access

      first_name: STRING
36      -- The person's first name.

      last_name: STRING
39      -- The person's last name.

      age: INTEGER
42      -- The person's age.

    invariant
45    age_non_negative: age >= 0
      first_name_exists: not first_name.is_empty
      last_name_exists: not last_name.is_empty
```

3

```
48  end
```

Listing 1.1: The PERSON class

There are three very important classes in ABEL:

- The deferred class `PS_REPOSITORY` provides an abstraction to the actual storage mechanism. It can only be used for read operations.

- The `PS_TRANSACTION` class represents a transaction and can be used to execute read, insert and update operations. Any `PS_TRANSACTION` object is bound to a `PS_REPOSITORY`.

- The `PS_OBJECT_QUERY [G]` class is used to describe a read operation over objects of type `G`. You can execute such a query in the `PS_EXECUTOR`. The result will be objects of type `G`.

To start using the library, we first need to create a `PS_REPOSITORY`. For this tutorial we are going to use an in-memory repository to avoid setting up any external database. Each ABEL backend will ship a repository factory class to make initialization easier. The factory for the in-memory repository is called `PS_IN_MEMORY_REPOSITORY_FACTORY`.

```
   class START

3  create
     make

6  feature {NONE} -- Initialization

     make
9        -- Initialization for 'Current'.
      local
        factory: PS_IN_MEMORY_REPOSITORY_FACTORY
12    do
       create factory
       repository := factory.new_repository
15
       create criterion_factory
       explore
18    end

   repository: PS_REPOSITORY
21    -- The main repository.
```

4

```
        end
24
  end
```

Listing 1.2: *The START class*

We will use *criterion_factory* later in this tutorial. The feature *explore* will guide us through the rest of this API tutorial and show the possibilities in ABEL.

Chapter 2

Basic operations

2.1 Inserting

You can insert a new object using feature *insert* in *PS_TRANSACTION*. As every write operation in ABEL needs to be embedded in a transaction, you first need to create a *PS_TRANSACTION* object. Let's add three new persons to the database:

```
   insert_persons
      -- Populate the repository with some person objects.
3  local
      p1, p2, p3: PERSON
      transaction: PS_TRANSACTION
6  do
       -- Create persons
      create p1.make (...)
9  create ...

       -- We first need a new transaction.
12 transaction := repository.new_transaction

       -- Now we can insert all three persons.
15 transaction.insert (p1)
   transaction.insert (p2)
   transaction.insert (p3)
18
       -- Don't forget to commit.
   transaction.commit
21 end
```

Listing 2.1: *Insertion code.*

2.2 Querying

A query for objects is done by creating a *PS_OBJECT_QUERY [G]* object and executing it using features of *PS_REPOSITORY* or *PS_TRANSACTION*. The generic parameter *G* denotes the type of objects that should be queried.

After a successful execution of the query, you can iterate over the result using the **across** syntax. The feature *print_persons* below shows how to get and print a list of persons from the repository:

```
  print_persons
     -- Print all persons in the repository
3   local
     query: PS_OBJECT_QUERY[PERSON]
   do
6     -- First create a query for PERSON objects.
     create query.make

9     -- Execute it against the repository.
     repository.execute_query (query)

12    -- Iterate over the result.
     across
       query as person_cursor
15   loop
       print (person_cursor.item)
     end
18
     -- Don't forget to close the query.
     query.close
21   end
```

Listing 2.2: Print all PERSON objects.

In a real database the result of a query may be very big, and you are probably only interested in objects that meet certain criteria, e.g. all persons of age 20. You can read more about it in Chapter 3.

Please note that ABEL does not enforce any kind of order on a query result.

2.3 Updating

Updating an object is done through feature *update* in *PS_TRANSACTION*. Like the insert operation, an update needs to happen within a transaction.

Note that in order to *update* an object, we first have to retrieve it.

Let's update the *age* attribute of Berno Citrini by celebrating his birth-day:

```
  update_berno_citrini
      -- Increase the age of Berno Citrini by one.
3   local
      query: PS_OBJECT_QUERY[PERSON]
      transaction: PS_TRANSACTION
6     berno: PERSON
    do
      print ("Updating Berno Citrini's age by one.%N")
9
        -- Create query and transaction.
      create query.make
12    transaction := repository.new_transaction

        -- As we're doing a read followed by a write, we
15      -- need to execute the query within a transaction.
      transaction.execute_query (query)

18      -- Search for Berno Citrini
      across
        query as cursor
21    loop
        if cursor.item.first_name ~ "Berno" then
          berno := cursor.item
24
          -- Change the object.
          berno.celebrate_birthday
27
          -- Perform the database update.
          transaction.update (berno)
30      end
      end

33    query.close
      transaction.commit
    end
```

Listing 2.3: Update Berno Citrini's age.

To perform an update the object first needs to be retrieved or inserted within the same transaction. Otherwise ABEL cannot map the Eiffel object to its database counterpart (see also Section 2.5).

2.4 Deleting

ABEL does not support explicit deletes any longer, as it is considered dangerous for shared objects. Instead of deletion it is planned to introduce a garbage collection mechanism in the future.

2.5 Dealing with Known Objects

Within a transaction ABEL keeps track of objects that have been inserted or queried. This is important because in case of an update, the library internally needs to map the object in the current execution of the program to its specific entry in the database.

Because of that, you can't update an object that is not yet known to ABEL. As an example, the following functions will fail:

```
   failing_update
      -- Trying to update a new person object.
3   local
      bob: PERSON
      transaction: PS_TRANSACTION
6   do
      create bob.make ("Robert", "Baratheon")
      transaction := repository.new_transaction
9      -- Error: Bob was not inserted / retrieved before.
      transaction.update (bob)
      transaction.commit
12   end

   update_after_commit
15      -- Update after transaction committed.
      local
      joff: PERSON
18      transaction: PS_TRANSACTION
      do
      create joff.make ("Joffrey", "Baratheon")
21      transaction := repository.new_transaction
      transaction.insert (joff)
      transaction.commit
24

      joff.celebrate_birthday

27        -- Prepare can be used to restart a transaction.
```

```
      transaction.prepare

30      -- Error: Joff was not inserted / retrieved before.
      transaction.update (joff)

33      -- Note: After commit and prepare, 'transaction'
        -- represents a completely new transaction.
   end
```

Listing 2.4: Common pitfalls with update.

The feature *is_persistent* in *PS_TRANSACTION* can tell you if a specific object is known to ABEL and hence has a link to its entry in the database.

Chapter 3

Advanced Queries

3.1 The query mechanism

As you already know from Section 2.2, queries to a database are done by creating an object of type *PS_OBJECT_QUERY[G]* and executing it against a *PS_TRANSACTION* or *PS_REPOSITORY*. The actual value of the generic parameter *G* determines the type of the objects that will be returned. At the moment descendants of *G* will not be loaded, but this behaviour may change in the future.

ABEL will by default load an object completely, meaning all objects that can be reached by following references will be loaded as well (see also Chapter 4).

3.2 Criteria

You can filter your query results by setting criteria in the query object, using feature *set_criterion* in *PS_OBJECT_QUERY*. There are two types of criteria: predefined and agent criteria.

3.2.1 Predefined Criteria

When using a predefined criterion you pick an attribute name, an operator and a value. During a read operation, ABEL checks the attribute value of the freshly retrieved object against the value set in the criterion, and filters away objects that don't satisfy the criterion.

Most of the supported operators are pretty self-describing (see class *PS_CRITERION_FACTORY* in Section 3.2.3). An exception could be the **like** operator, which does pattern-matching on strings. You can provide the

like operator with a pattern as a value. The pattern can contain the wild-card characters `*` and `?`. The asterisk stands for any number (including zero) of undefined characters, and the question mark means exactly one undefined character.

You can only use attributes that are strings or numbers, but not every type of attribute supports every other operator. Valid combinations for each type are:

- Strings: =, like

- Any numeric value: $=, <, <=, >, >=$

- Booleans: =

Note that for performance reasons it is usually better to use predefined criteria, because they can be compiled to SQL and hence the result can be filtered in the database.

3.2.2 Agent Criteria

An agent criterion will filter the objects according to the result of an agent applied to them.

The criterion is initialized with an agent of type *PREDICATE [ANY, TUPLE [ANY]]*. There should be either an open target or a single open argument, and the type of the objects in the query result should conform to the agent's open operand. For an example see Section 3.2.3.

3.2.3 Creating criteria objects

The criteria instances are best created using the *CRITERION_FACTORY* class.

The main features of the class are the following:

```
class
  PS_CRITERION_FACTORY
create
  default_create

feature -- Creating a criterion

  new_uniform alias "[]" (tuple: TUPLE [ANY]): PS_CRITERION
    -- Creates a new criterion according to a 'tuple'
    -- containing either a single PREDICATE or three
    -- values of type [STRING, STRING, ANY].
```

```
12
   new_agent (a_predicate: PREDICATE [ANY, TUPLE [ANY]]):
     PS_CRITERION
    -- Creates an agent criterion.
15
   new_predefined (object_attribute: STRING;
    operator: STRING; value: ANY): PS_CRITERION
18   -- Creates a predefined criterion.

  feature -- Operators
21
   equals: STRING = "="

24 greater: STRING = ">"

   greater_equal: STRING = ">="
27
   less: STRING = "<"

30 less_equal: STRING = "<="

   like_string: STRING = "like"
33
  end
```

Listing 3.1: The CRITERION_FACTORY class interface

Assuming you have an object `f`: `PS_CRITERION_FACTORY`, to create a new criterion you have two possibilities:

- The "traditional" way

    - `f.new_agent (agent an_agent)`
    - `f.new_predefined (an_attr_name, an_operator, a_val)`

- The "syntactic sugar" way

    - `f[[an_attr_name, an_operator, a_value]]`
    - `f[[agent an_agent]]`

caption=The PS_CRITERION_FACTORY interface

```eiffel
   create_criteria_traditional : PS_CRITERION
3    -- Create a new criteria using the traditional approach.
   do
     -- for predefined criteria
6    Result:=
       factory.new_predefined ("age", factory.less, 5)

9    -- for agent criteria
   Result :=
       factory.new_agent (agent age_more_than (?, 5))
12   end

   create_criteria_double_bracket : PS_CRITERION
15   -- Create a new criteria using the double bracket syntax
      .
   do
     -- for predefined criteria
18   Result:= factory[["age", factory.less, 5]]

     -- for agent criteria
21   Result := factory[[agent age_more_than (?, 5)]]
   end

24 age_more_than (person: PERSON; age: INTEGER): BOOLEAN
   -- An example agent
   do
27   Result:= person.age > age
   end
```

Listing 3.2: *Different ways of creating criteria.*

3.2.4 Combining criteria

You can combine multiple criterion objects by using the standard Eiffel logical operators. For example, if you want to search for a person called "Albo Bitossi" with $age <= 20$, you can just create a criterion object for each of the constraints and combine them:

```eiffel
1

   composite_search_criterion : PS_CRITERION
   -- Combining criterion objects.
4  local
     first_name_criterion: PS_CRITERION
```

14

```
         last_name_criterion: PS_CRITERION
 7       age_criterion: PS_CRITERION
      do
        first_name_criterion:=
10        factory[[ "first_name", factory.equals, "Albo" ]]

        last_name_criterion :=
13        factory[[ "last_name", factory.equals, "Bitossi" ]]

        age_criterion :=
16        factory[[ agent age_more_than (?, 20) ]]

      Result := first_name_criterion and last_name_criterion
          and not age_criterion
19

      -- Using double brackets for compactness.
      Result := factory[[ "first_name", "=", "Albo" ]]
22      and factory[[ "last_name", "=", "Bitossi" ]]
        and not factory[[ agent age_more_than (?, 20) ]]
      end
```

***Listing 3.3:** Combining criteria.*

ABEL supports the three standard logical operators **AND**, **OR** and **NOT**.
The precedence rules are the same as in Eiffel, which means that **NOT** is
stronger than **AND**, which in turn is stronger than **OR**.

Chapter 4

Dealing with references

In ABEL, a basic type is an object of type *STRING*, *BOOLEAN*, *CHARACTER* or any numeric class like *REAL* or *INTEGER*. The *PERSON* class only has attributes of a basic type. However, an object can contain references to other objects. ABEL is able to handle these references by storing and reconstructing the whole object graph (an object graph is roughly defined as all the objects that can be reached by recursively following all references, starting at some root object).

4.1   Inserting objects with dependencies

Let's look at the new class *CHILD*:

```
class
  CHILD

create
  make

feature {NONE} -- Initialization

  make (first, last: STRING)
      -- Create a new child.
    require
      first_exists: not first.is_empty
      last_exists: not last.is_empty
    do
      first_name := first
      last_name := last
```

```eiffel
18      age := 0
    ensure
      first_name_set: first_name = first
21    last_name_set: last_name = last
      default_age: age = 0
    end
24

  feature -- Access

27 first_name: STRING
      -- The child's first name.

30 last_name: STRING
      -- The child's last name.

33 age: INTEGER
      -- The child's age.

36 father: detachable CHILD
      -- The child's father.

39 feature -- Element Change

   celebrate_birthday
42    -- Increase age by 1.
    do
      age := age + 1
45    ensure
      age_incremented_by_one: age = old age + 1
    end
48

   set_father (a_father: CHILD)
      -- Set a father for the child.
51    do
      father := a_father
    ensure
54    father_set: father = a_father
    end

57 invariant
   age_non_negative: age >= 0
   first_name_exists: not first_name.is_empty
60 last_name_exists: not last_name.is_empty
```

17

```
end
```

Listing 4.1: The CHILD class.

This adds in some complexity: instead of having a single object, ABEL has to insert a *CHILD*'s mother and father as well, and it has to repeat this procedure if their parent attribute is also attached. The good news are that the examples above will work exactly the same.

However, there are some additional caveats to take into consideration. Let's consider a simple example with *CHILD* objects "Baby Doe", "John Doe" and "Grandpa Doe". From the name of the object instances you can already guess what the object graph looks like:

$$BabyDoe \xrightarrow{father} JohnDoe \xrightarrow{father} GrandpaDoe$$

Now if you insert "Baby Doe", ABEL will by default follow all references and insert every single object along the object graph, which means that "John Doe" and "Grandpa Doe" will be inserted as well. This is usually the desired behavior, as objects are stored completely that way, but it also has some side effects we need to be aware of:

- Assume an insert of "Baby Doe" has happened to an empty database. If you now query the database for *CHILD* objects, it will return exactly the same object graph as above, but the query result will actually have three items, as the object graph consists of three single *CHILD* objects.

- After inserting "Baby Doe", an insert of "John Doe" or "Grandpa Doe" will result in a precondition violation, because they have already been inserted as references of "Baby Doe".

In our main tutorial class *START* we have the following two features that show how to deal with object graphs. You will notice it is very similar to the corresponding routines for the flat *PERSON* objects.

```
   insert_children
      -- Populate the repository with some children objects.
3    local
      c1, c2, c3: CHILD
      transaction: PS_TRANSACTION
6    do
       -- Create the object graph.
     create c1.make ("Baby", "Doe")
```

18

```
 9     create c2.make ("John", "Doe")
       create c3.make ("Grandpa", "Doe")
       c1.set_father (c2)
12     c2.set_father (c3)

       print ("Insert 3 children in the database.%N")
15     transaction := repository.new_transaction

         -- It is sufficient to just insert "Baby Joe",
18       -- as the other CHILD objects are (transitively)
         -- referenced and thus inserted automatically.
       transaction.insert (c1)
21     transaction.commit
     end

24 print_children
       -- Print all children in the repository
     local
27     query: PS_QUERY[CHILD]
     do
       create query.make
30     repository.execute_query (query)

         -- The result will also contain
33       -- all referenced CHILD objects.
     across
       query as person_cursor
36     loop
         print (person_cursor.item)
       end
39
       query.close
     end
```

Listing 4.2: *Dealing with object graphs.*

4.2   Going deeper in the Object Graph

ABEL has no limits regarding the depth of an object graph, and it will detect and handle reference cycles correctly. You are welcome to test ABEL's capability with very complex objects, however please keep in mind that this may impact performance significantly.

Chapter 5

Tuple queries

Consider a scenario in which you just want to have a list of all first names of `CHILD` objects in the database. Loading every attribute of each object of type `CHILD` might lead to a very bad performance, especially if there is a big object graph attached to each `CHILD` object.

To solve this problem ABEL allows queries which return data in `TUPLE` objects. Tuple queries are executed by calling `execute_tuple_query` (`a_tuple_query`) in either `PS_REPOSITORY` or `PS_TRANSACTION`, where `a_tuple_query` is of type `PS_TUPLE_QUERY [G]`. The result is an iteration cursor over a list of tuples in which the attributes of an object are stored.

5.1 Tuple queries and projections

The `projection` feature in a `PS_TUPLE_QUERY` defines which attributes shall be included in the result `TUPLE`. Additionally, the order of the attributes in the projection array is the same as the order of the elements in the result tuples.

By default, a `PS_TUPLE_QUERY` object will only return values of attributes which are of a basic type, so no references are followed during a retrieve. You can change this default by calling `set_projection`. If you include an attribute name whose type is not a basic one, ABEL will actually retrieve and build the attribute object, and not just another tuple.

5.2 Tuple queries and criteria

You are restricted to use predefined criteria in tuple queries, because agent criteria expect an object and not a tuple. You can still combine them with

logical operators, and even include a predefined criterion on an attribute that is not present in the projection list. These attributes will be loaded internally to check if the object satisfies the criterion, and then they are discarded for the actual result.

5.3   Example

```
    explore_tuple_queries
3       -- See what can be done with tuple queries.
    local
      query: PS_TUPLE_QUERY [CHILD]
6     transaction: PS_TRANSACTION
      projection: ARRAYED_LIST [STRING]
    do
9       -- Tuple queries are very similar to normal queries.
        -- I.e. you can query for CHILD objects by creating
        -- a PS_TUPLE_QUERY [CHILD]
12    create query.make

        -- It is also possible to add criteria. Agent
           criteria
15      -- are not supportedfor tuple queries however.
        -- Lets search for CHILD objects with last name Doe.
      query.set_criterion (criterion_factory
18      [["last_name", criterion_factory.equals, "Doe"]])

        -- The big advantage of tuple queries is that you can
21      -- define which attributes should be loaded.
        -- Thus you can avoid loading a whole object graph
        -- if you're just interested in e.g. the first name.
24    create projection.make_from_array (<<"first_name">>)
      query.set_projection (projection)

27      -- Execute the tuple query.
      repository.execute_tuple_query (query)

30      -- The result of the query is a TUPLE containing the
        -- requested attribute.

33    print ("Print all first names using a tuple query:%N")
```

```
      across
36      query as cursor
      loop
        -- It is possible to downcast the TUPLE
39      -- to a tagged tuple with correct type.
      check
        attached {TUPLE [first_name: STRING]}
42        cursor.item as tuple
      then
        print (tuple.first_name + "%N")
45      end
      end
      end
```

Listing 5.1: Using tuple queries.

Chapter 6

Error handling

As ABEL is dealing with I/O and databases, runtime errors may happen. The library will in general raise an exception in case of an error and expose the error to the library user as an *PS_ERROR* object.

ABEL maps database specific error messages to its own representation for errors, which is a hierarchy of classes rooted at *PS_ERROR*. The following list shows all error classes that are currently defined with some examples (the *PS_* prefix is omitted for brevity):

- *CONNECTION_SETUP_ERROR*: No internet link, or a deleted serialization file.

- *AUTHORIZATION_ERROR*: Usually a wrong password.

- *BACKEND_ERROR*: An unrecoverable error in the storage backend, e.g. a disk failure.

- *INTERNAL_ERROR*: Any error happening inside ABEL.

- *PS_OPERATION_ERROR*: For invalid operations, e.g. no access rights to a table.

- *TRANSACTION_ABORTED_ERROR*: A conflict between two transactions.

- *MESSAGE_NOT_UNDERSTOOD_ERROR*: Malformed SQL or JSON statements.

- *INTEGRITY_CONSTRAINT_VIOLATION_ERROR*: The operation violates an integrity constraint in the database.

- *EXTERNAL_ROUTINE_ERROR*: An SQL routine or triggered action has failed.

- *VERSION_MISMATCH*: The stored version of an object isn't compatible any more to the current type.

If you want to handle an error, you have to add a **rescue** clause somewhere in your code.

You can get the actual error from *PS_TRANSACTION*.*last_error* or - due to the fact that *PS_ERROR* inherits from *DEVELOPER_EXCEPTION* - by performing an object test on *EXCEPTION_MANAGER*.*last_exception*.

For your convenience, there is a visitor pattern for all ABEL error types. You can just implement the appropriate functions and use it for your error handling code.

The following code shows an example:

```
  class
3 MY_PRIVATE_VISITOR

  inherit
6 PS_DEFAULT_ERROR_VISITOR
    redefine
      visit_transaction_aborted_error,
9     visit_connection_setup_error
    end

12 feature -- Status report

  shall_retry: BOOLEAN
15   -- Should my client retry the operation?

  feature -- Visitor features
18
  visit_transaction_aborted_error (tae:
    PS_TRANSACTION_ABORTED_ERROR)
    -- Visit a transaction aborted error
21  do
    shall_retry := True
    end
24
  visit_connection_setup_error (cse:
    PS_CONNECTION_SETUP_ERROR)
    -- Visit a connection setup error
27  do
    notify_user_of_abort
    shall_retry:=False
```

```eiffel
30      end

     feature {NONE} -- Pseudocode
33

       notify_user_of_abort
           -- Notify the user that the operation has been aborted
36       do
         end

39   end

     class
42     EXAMPLE

     feature
45

       my_visitor: MY_PRIVATE_VISITOR
         -- A user-defined visitor to react to an error.
48

       do_something_with_error_handling
         -- Perform some operations. Deal with errors in case of
           a problem.
51       local
           transaction: PS_TRANSACTION
         do
54         -- Some complicated operations
         rescue
           my_visitor.visit (executor.last_error)
57         if my_visitor.shall_retry then
             retry
           else
60           -- The exception propagates upwards, and maybe
             -- another feature can handle it
           end
63       end
       end
```

Listing 6.1: Sample error handling using a visitor.
